Abstract

The stability analysis in this mathematical model was related to the infection of the Coronavirus Disease 2019 (Covid-19). In this mathematical model there were two balance points, namely the point of balance free from Covid-19 and the one infected with Covid-19. The stability of the equilibrium point was influenced by all parameters, i.e. target cells die during each cycle, number of target cells at \( t' = 0 \), target cells infected during each cycle based on virion unit density, effective surface area of the network, the ratio of the number of virus particles to the number of virions, infected cells die during each cycle, the number of virus particles produced by each infected cell during each cycle, and virus particles die during each cycle. In the simulation model, immunity is divided into high, medium and low immunity. For high, moderate and low immunity, respectively, the highest number of target cells is in high, medium and low immunity, whereas for the number of infected cells and the number of Covid-19, it is in the opposite sequence of the number of target cells.

Keywords: Coronavirus Disease 2019; Equilibrium point stability; target cells and infected cells.

INTRODUCTION

Coronavirus Disease 2019 (Covid-19) was first known to infect residents in Wuhan City, China, and was notified by the Chinese Government to WHO in December 2019 (Sugiyanto & Abrori, 2020). Covid-19 belongs to subfamily Orthocoronavirinae, family Coronaviridae, and order Nidovirales (Tan et. al., 2020). About 80% of Covid-19 illness show mild symptoms and 20% have severe symptoms. Some of the 20% patients who contract Covid-19 develop severe pneumonia, sometimes with acute respiratory distress, which can lead to organ failure and death.

The stability analysis of mathematical modeling is used to determine the recovery period of Covid-19 patients. There are many factors that determine a person would get into mild, severe or severe symptoms. We can classify these symptoms into three things depend on the immunity of the Covid-19 patient. In this modeling, categorization were done using the T – I – V model. The target cell subpopulation (T) is cells in several organs, such as the lungs, heart, arteries, intestines and kidneys. The Infected cell subpopulation (I) is a cell that is infected through a receptor on the surface called Angiotsensin Converting Enzyme 2 (ACE2) (Diaz, 2020). Target cells were epithelial cells in all of these organs. This target cell was ACE2. The conversion of angiotensin II (vasoconstruction peptide) to angiotensin 1-7 (vasodilator) was catalyzed by ACE2 (Zhang et. al., 2020), 83% of normal lung cells express ACE2, namely type II alveolar epithelial cells (AECII), which make these cells viral reservoirs. The spike protein (shaped like a nail) stuck to the surface of the SARS-CoV virus (Zoufaly et. al., 2020). The ACE2 enzyme attaches to the cell membranes of several organs (Bourgonje et. al, 2020).

STABILITY ANALYSIS

The Mathematical Model obtained in System (1) refers to Du and Yuan's (2020) paper.

\[
\frac{dT}{dt} = (d\tau)T_0 - (d\tau)T - \frac{(k\tau)}{A\alpha} VT
\]

(1a)

\[
\frac{dT}{dt} = \frac{(k\tau)}{A\alpha} VT -(\delta\tau)I
\]

(1b)

\[
\frac{dV}{dt} = (pr)I - (c\tau)V
\]

(1c)

Description of the target cell subpopulation, Covid-19 infected cells, virus population and parameters are shown in Table 1.
Table 1. Target cell subpopulation, Covid-19 infected cells, virus population and parameters.

**Theorem 1. Equilibrium Point**

There are two equilibrium points of System (1), namely: free from the Covid-19 virus and infected with the Covid-19 virus. The Covid-19 virus-free equilibrium point is

\[
EP_0 = (T, I, V) = (T_0, 0,0).
\]

The equilibrium point for contracting the Covid-19 virus is

\[
EP_1 = (T, I, V) = (a_1, a_2, a_3),
\]

where

\[
a_1 = \frac{A\alpha(\delta t)(ct)}{(kt)(pr)}, \quad a_2 = \frac{(kt)(dr)T_0(pr) - (\delta t)(ct)(dr)Aa}{(pr)(\delta t)(kt)}, \quad a_3 = \frac{(kt)(dr)T_0(pr) - (\delta t)(ct)(dr)Aa}{(\delta t)(ct)(kt)}.
\]

**Proof.**

From Equation (1a) and \( \frac{dT}{dt} = 0 \), we get

\[
T = \frac{(dr)T_0Aa}{(dr)Aa + (\delta t)V}.
\] (2)

From Equation (1c) and \( \frac{dv}{dt} = 0 \) obtained

\[
I = \frac{(ct)}{(pr)}V.
\] (3)

From \( \frac{dv}{dt} = 0 \) and substituting equations (2) and (3) into equation (1), we get

\[
V = 0 \quad \text{or} \quad V = \frac{(dr)[(kt)T_0(pr) - (\delta t)(ct)Aa]}{(\delta t)(ct)(kt)} = a_3.
\] (4)

From Equation (2) and Equation (4), we get

\[
T = T_0.
\] (6)

From Equation (3) and Equation (4), we get

\[
I = 0.
\] (7)

From Equations (6), (7) and (4) it is proven that the Covid-19 virus-free equilibrium point is \( EP_0 \).

If Equation (5) is substituted into Equation (2), then we get

\[
T = \frac{A\alpha(\delta t)(ct)}{(kt)(pr)} = a_1.
\] (8)

If Equation (8) is substituted into Equation (3), then we get

\[
I = \frac{(kt)(dr)T_0(pr) - (\delta t)(ct)(dr)Aa}{(pr)(\delta t)(kt)} = a_2.
\] (9)

From Equations (8), (9) and (5) it is proven that the equilibrium point for contracting the Covid-19 virus is \( EP_1 \).

From Theorem 1 it can be conveyed, if there is no Covid-19 virus then someone will be safe or someone is virus free, and if there is a virus then a person's healing point is influenced by all parameters. Virus-free can be achieved if there is no person carrying the virus or complying with health procedures such as wearing a mask, keeping a distance and washing hands as often as possible. When a person gets a virus, only the immune (target cells) can fight the infected cells.

**Theorem 2. Existence of the Equilibrium Point**

Existence \( EP_0 \) fulfilled in any non-negative number parameter and existence \( EP_1 \) fulfilled if

\[
(kt)T_0(pr) - (\delta t)(ct)Aa > 0.
\]

**Proof.**

From Theorem 1, that existence \( EP_0 \) and \( EP_1 \) proven. ■

From Theorem 2 it can be seen that all parameters do not affect the existence of the equilibrium point \( EP_0 \). All parameters are target cells die during each cycle, number of target cells at \( t' = 0 \), target cells infected during each cycle based on virion unit density, effective surface area of the network, the ratio of the number of virus particles to the number of virions, infected cells die during each cycle, the number of virus particles produced by each infected cell during each cycle, and virus particles die during each cycle. This means that if a person is not exposed to the Covid-19 virus, the target cells would not be affected or the condition of a person is healthy without the virus. For someone who is infected with the virus, all parameters affect the existence of the equilibrium point \( EP_0 \). This means that a person's condition will remain
healthy or even die depending on the target cells working well or not.

**Theorem 3.** Stability of the Equilibrium Point

1. If \( \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right) - ((\delta \tau) + (c \tau))} \), then the equilibrium point \( EP_0 \) is locally asymptotically stable.

2. If \( \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau)(a_1)}{Aa} \right) - ((\delta \tau) + (c \tau))} < 0 \), then the equilibrium point \( EP_1 \) is locally asymptotically stable.

**Proof.**

For example, in System (1) it is written

\[
\begin{align*}
f_1 &= \frac{dT}{d\tau} = (d \tau) T_0 - (d \tau) T - \left( \frac{(k \tau)}{Aa} \right) VT \\
f_2 &= \frac{dT}{d\tau} = \left( \frac{(k \tau)}{Aa} \right) VT - (\delta \tau) I \\
f_3 &= \frac{dT}{d\tau} = (p \tau) I - (c \tau) V
\end{align*}
\]

Jacobian matrix function \( f \) from System (10) written can be obtained by first performing the partial derivation of the functions

\[
\begin{align*}
f_1 &= (T, I, V) \\
f_2 &= (T, I, V) \\
f_3 &= (T, I, V)
\end{align*}
\]

as follows.

(i). Partial derivative \( f_1 \) with respect to \( T, I, V \) namely:
\[
\frac{\partial f_1}{\partial T} = -(d \tau) - \left( \frac{(k \tau)}{Aa} \right) V; \quad \frac{\partial f_1}{\partial I} = 0; \quad \frac{\partial f_1}{\partial V} = 0;
\]

(ii). Partial derivative \( f_2 \) with respect to \( T, I, V \) namely:
\[
\frac{\partial f_2}{\partial T} = \left( \frac{(k \tau)}{Aa} \right) V; \quad \frac{\partial f_2}{\partial I} = -(\delta \tau); \quad \frac{\partial f_2}{\partial V} = \left( \frac{(k \tau)}{Aa} \right) T;
\]

(iii). Partial derivative \( f_3 \) with respect to \( T, I, V \) namely:
\[
\frac{\partial f_3}{\partial T} = 0; \quad \frac{\partial f_3}{\partial I} = (p \tau); \quad \frac{\partial f_3}{\partial V} = -(c \tau);
\]

The Jacobian matrix is
\[
J(T, I, V) = \begin{bmatrix}
-(d \tau) - \left( \frac{(k \tau)}{Aa} \right) V & 0 & 0 \\
0 & -(\delta \tau) & \left( \frac{(k \tau)}{Aa} \right) T \\
0 & (p \tau) & -(c \tau)
\end{bmatrix}
\]

(1) For \( EP_0 \), we get
\[
J(T_0, 0, 0) = \begin{bmatrix}
-(d \tau) & 0 & 0 \\
0 & -(\delta \tau) & \left( \frac{(k \tau)}{Aa} \right) (T_0) \\
0 & (p \tau) & -(c \tau)
\end{bmatrix}
\]

We find the eigenvalues of \( J(T_0, 0, 0) \) that is \( \lambda_i \), for \( i = 1, 2, 3 \), where
\[
J(T_0, 0, 0) - \lambda I = 0.
\]

We get the eigenvalues of the Jacobian Matrix which is represented by
\[
\lambda_1 = -(d \tau), \quad \lambda_2 = \frac{1}{2} - ((\delta \tau) + (c \tau)) - \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right)}, \quad \lambda_3 = \frac{1}{2} - ((\delta \tau) + (c \tau)) + \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right)}.
\]

We know that \( ((\delta \tau) - (c \tau))^2 \geq 0 \) and \( \frac{(k \tau)(p \tau) T_0}{Aa} > 0 \), so that \( ((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right) > 0 \).

Since the parameters are greater than zero, we get
\[
\lambda_1 < 0, \quad \lambda_2 < 0,
\]

and because \( \left( ((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right) > 0 \), then we get \( \lambda_3 = \frac{1}{2} - ((\delta \tau) - (c \tau)) \pm \sqrt{((\delta \tau) - (c \tau))^2 - 4 \left( (k \tau)(c \tau) - \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right) < 0. \right. \]

We get all negative eigenvalues, so that \( EP_0 \) is locally asymptotically stable.

(2) For \( EP_1 \), we get
\[
J(a_1, a_2, a_3) = \begin{bmatrix}
-(d \tau) - \left( \frac{(k \tau)}{Aa} \right) (a_3) & 0 & 0 \\
\left( \frac{(k \tau)}{Aa} \right) (a_3) & -(\delta \tau) & \left( \frac{(k \tau)}{Aa} \right) (a_1) \\
0 & (p \tau) & -(c \tau)
\end{bmatrix}
\]

We find the eigenvalues of \( J(a_1, a_2, a_3) \) that is \( \lambda_i \), for \( i = 1, 2, 3 \), where
\[
J (a_1, a_2, a_3) - \lambda I = 0.
\]

We get the eigenvalues of the Jacobian Matrix which is represented by
\[
\lambda_1 = -(d \tau) + \left( \frac{(k \tau)}{Aa} \right) (a_i), \quad \lambda_2 = \frac{1}{2} - ((\delta \tau) + (c \tau)) - \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau)(a_i)}{Aa} \right)}, \quad \lambda_3 = \frac{1}{2} - ((\delta \tau) + (c \tau)) + \sqrt{((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau)(a_i)}{Aa} \right)}.
\]

We know that \( ((\delta \tau) - (c \tau))^2 \geq 0 \) and \( \left( \frac{(k \tau)(p \tau) T_0}{Aa} \right) > 0 \), so that \( ((\delta \tau) - (c \tau))^2 + 4 \left( \frac{(k \tau)(p \tau)(a_i)}{Aa} \right) > 0 \).

Since the parameters are greater than zero, we get
\[
\lambda_1 < 0, \quad \lambda_2 < 0,
\]
and because \[ \sqrt{(\delta \tau - (c \tau))^2 + 4 \frac{(k \tau)(p \tau)(a_\tau)}{\alpha \tau}} < 0, \]
then we get \[ \lambda = \frac{1}{2} \left( -(\delta \tau + (c \tau)) + \sqrt{((\delta \tau - (c \tau))^2 + 4 \frac{(k \tau)[p \tau][a_\tau]}{\alpha \tau}} \right) < 0. \]
We get all negative eigenvalues, so that \( EP_1 \) is locally asymptotically stable.

From Theorem 3 the stability point is affected by all parameters. This means that a person will recover depending on the target cells that work. The better the target cells work, the healthier the person would be and those who have been infected with Covid-19 will recover.

### SIMULATION

The parameters in this simulation are taken from Du and Yuan’s (2020) paper. Table 2 shows the parameter values. In this simulation, we replace the symbol \((p \tau)\) with \(b\). This is because in Matlab there is no Insert Legend that can be written \((p \tau)\).

Table 2. Parameter values for simulation.

Target cells reflect the number of cells in people with three conditions, namely: low, moderate and high immunity conditions. Figure 1. Figure 2 and Figure 3 represent person with high immunity \( (p \tau) = b = 50 \), moderate immunity \( (p \tau) = b = 100 \), and low immunity \( (p \tau) = b = 150 \). Person with good immunity shows the target cell from 10,000,000 cells in 13.09 days to 101,800 cells. Person with moderate immunity shows the target cell from 10,000,000 cells in 8,514 days to 104,300 cells. Person with low immunity shows the target cell from 10,000,000 cells in 2,398 days to 105,000 cells. The order of decline in target cells from the longest to the fastest is good, medium and low immunity. Table 3 describes the descending order of the target cells.

Table 3. Target cell decrease.

Figure 2 shows the peak number of infected cells differed between individuals with high, moderate and low immunity. A person with low immunity on day 6,155 the number of infected is \( 7.146 \times 10^7 \) cell. A person with moderate immunity on day 7,685 the number of infected is \( 6.65 \times 10^7 \) cell. A person with high immunity on day 11.46 the number of infected is \( 5.655 \times 10^7 \) cell. Briefly, this explanation is in Table 4.

CONCLUSION

The stability of being free of the Covid-19 virus and infected with the virus is influenced by all parameters. The number of target cells, virus-infected cells and virus particles is affected by a person’s immunity. If a person has high immunity, the number of target cells would decrease slowly. Vice versa, if a person has low immunity, then the number of target cells will drop rapidly. In a person having low immunity, the infected cells and viruses will quickly increase in number compared to the one with high immunity.
